Project

Auslandsjob-Hilfe

A system that collects job offers from around the world for an extraordinary summer in 2027, checks them and ranks them against my own criteria.

n8n | Claude Code | GitHub Actions | Python

Thousands of openings on job boards, research stations, boatyards and ships. I am looking for one that really fits.

Doing this by hand is barely possible: every source looks different, details are missing, and many positions are only advertised for a few weeks.

Timing	**Start between 20 April and 15 June 2027**
Duration	**6 to 13 weeks**
Cost	**Programme fee of €500 at most**
Visa	**Realistic for an EU citizen**
Language	**German or English is enough**

Hard criteria filter offers out. Eleven soft criteria, such as how extraordinary it is or how hands-on the work is, decide the ranking.

Three steps, automated every day

1

Collect

Four sources are queried daily, covering Norway, Sweden, Australia and the US. Hand-researched offers are added on top. New, changed and closed positions are detected.

3,129 positions tracked

2

Assess

A pre-filter removes what clearly does not fit. Claude reads the remaining ads, summarises them and backs every fact with a quote. Rules check visa, duration and fees.

11 weighted criteria

3

Review

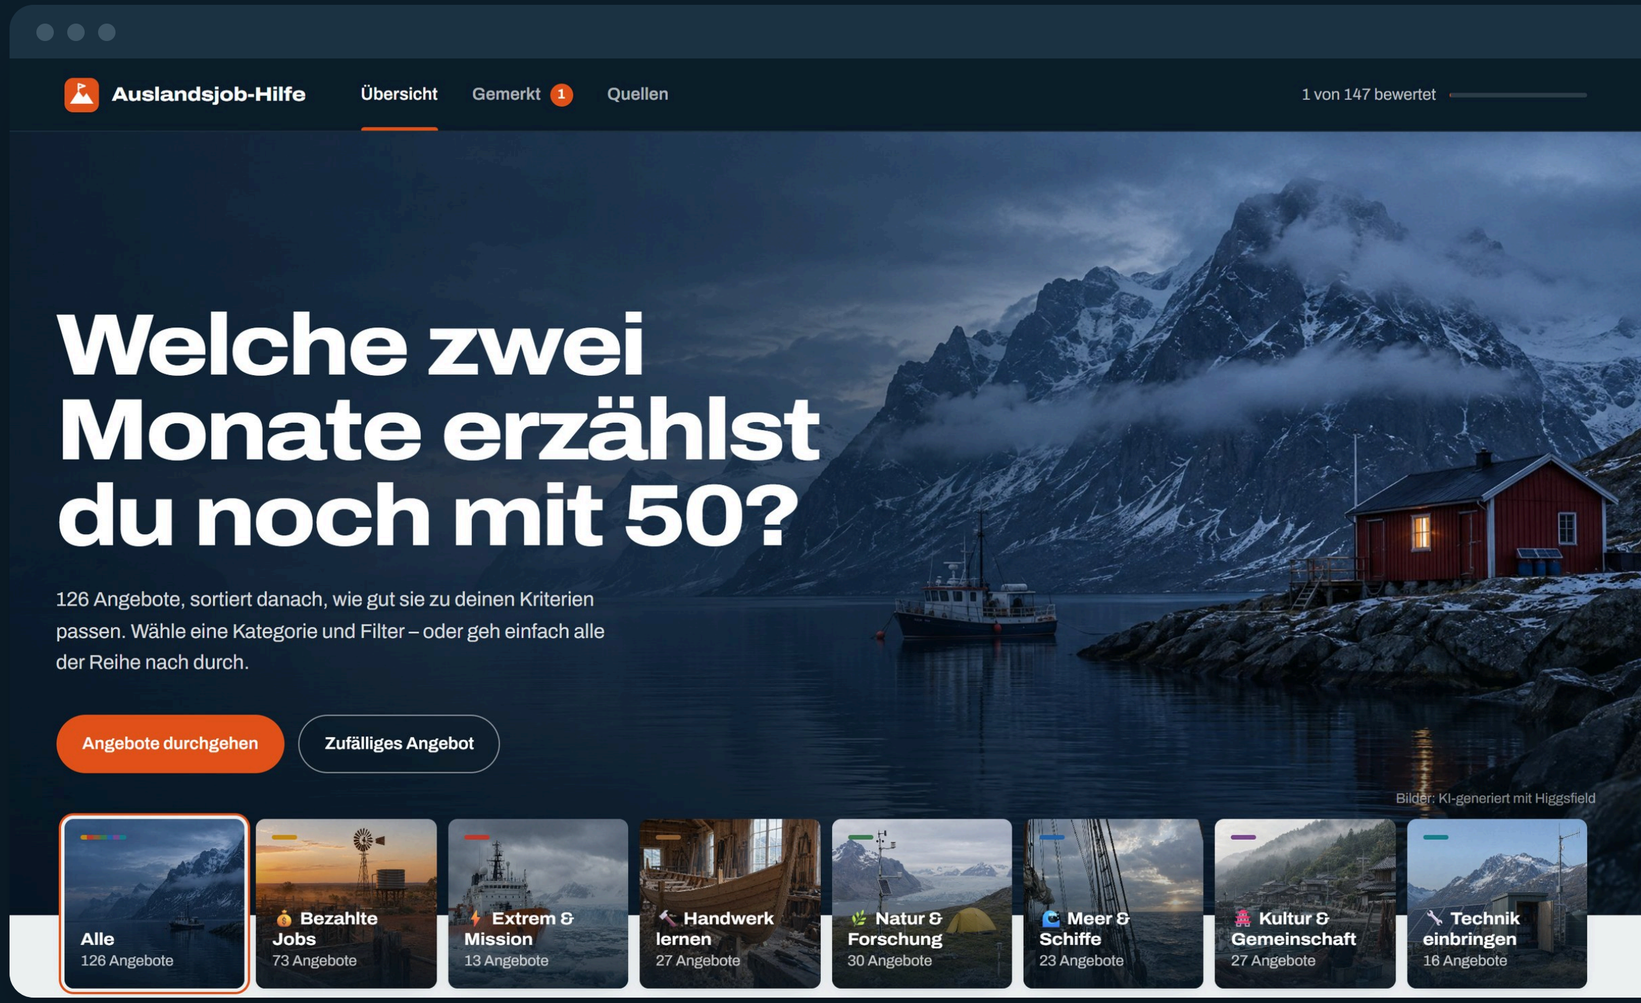

The best offers appear as cards in a web app, where I filter, rate and bookmark them. New matches arrive by email.

147 offers in the app

The overview

Every offer at a glance, ranked by how well it matches my criteria.

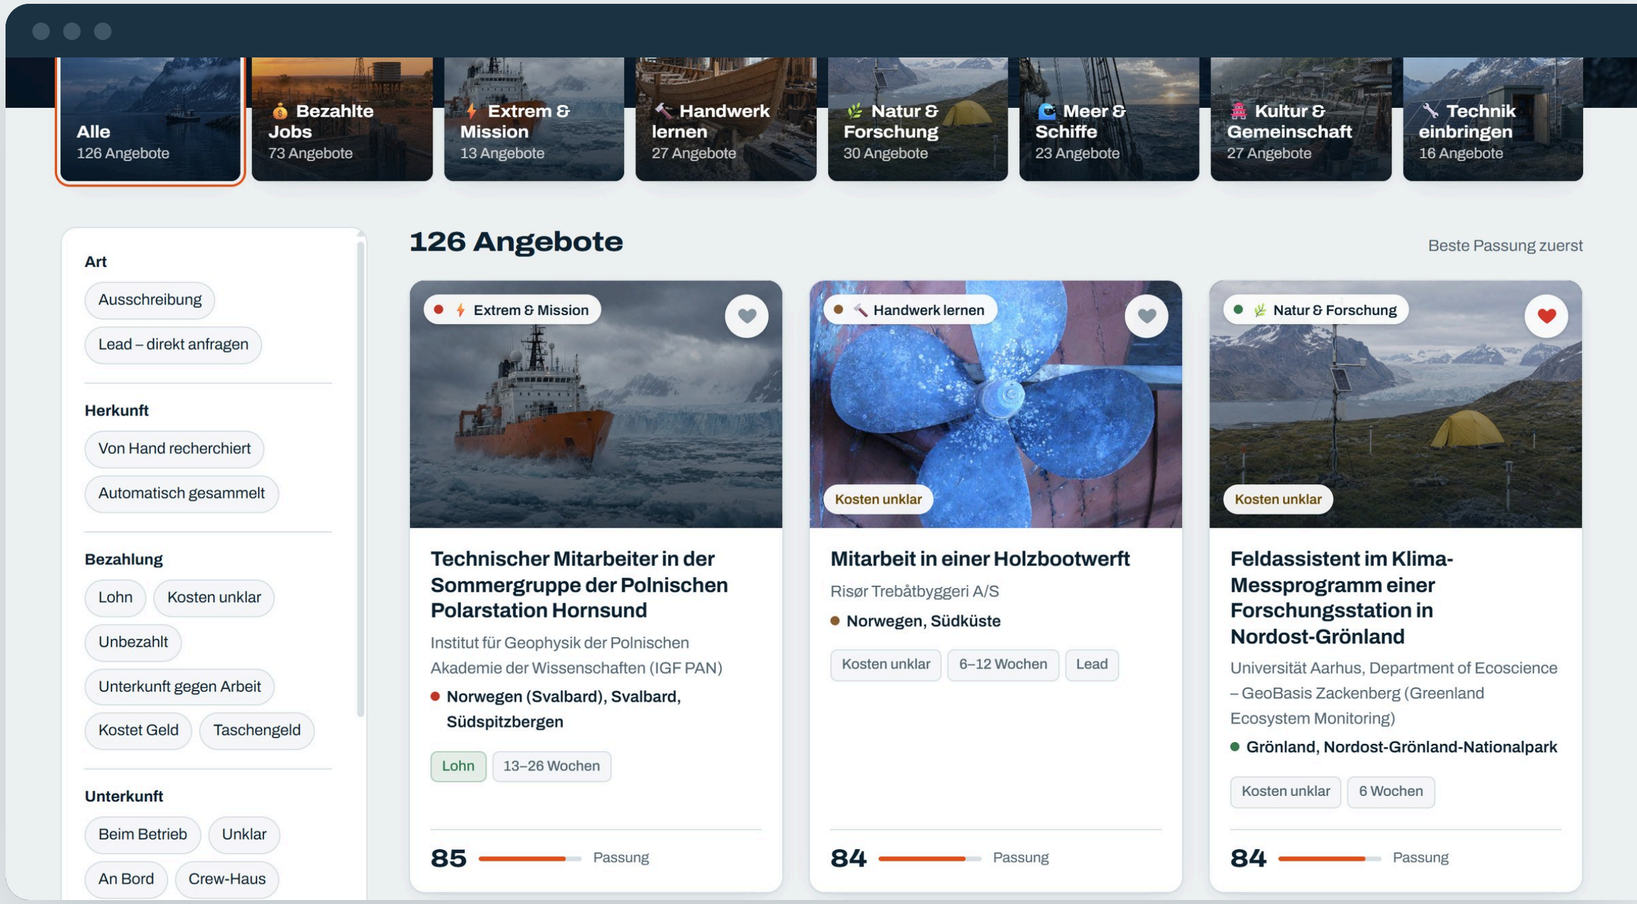

- Seven categories, from paid jobs to nature and research
- One button walks through all offers one by one
- Progress in the top right shows how many are rated

Filter, don’t search

Each card shows location, duration, pay and a match score from 0 to 100.

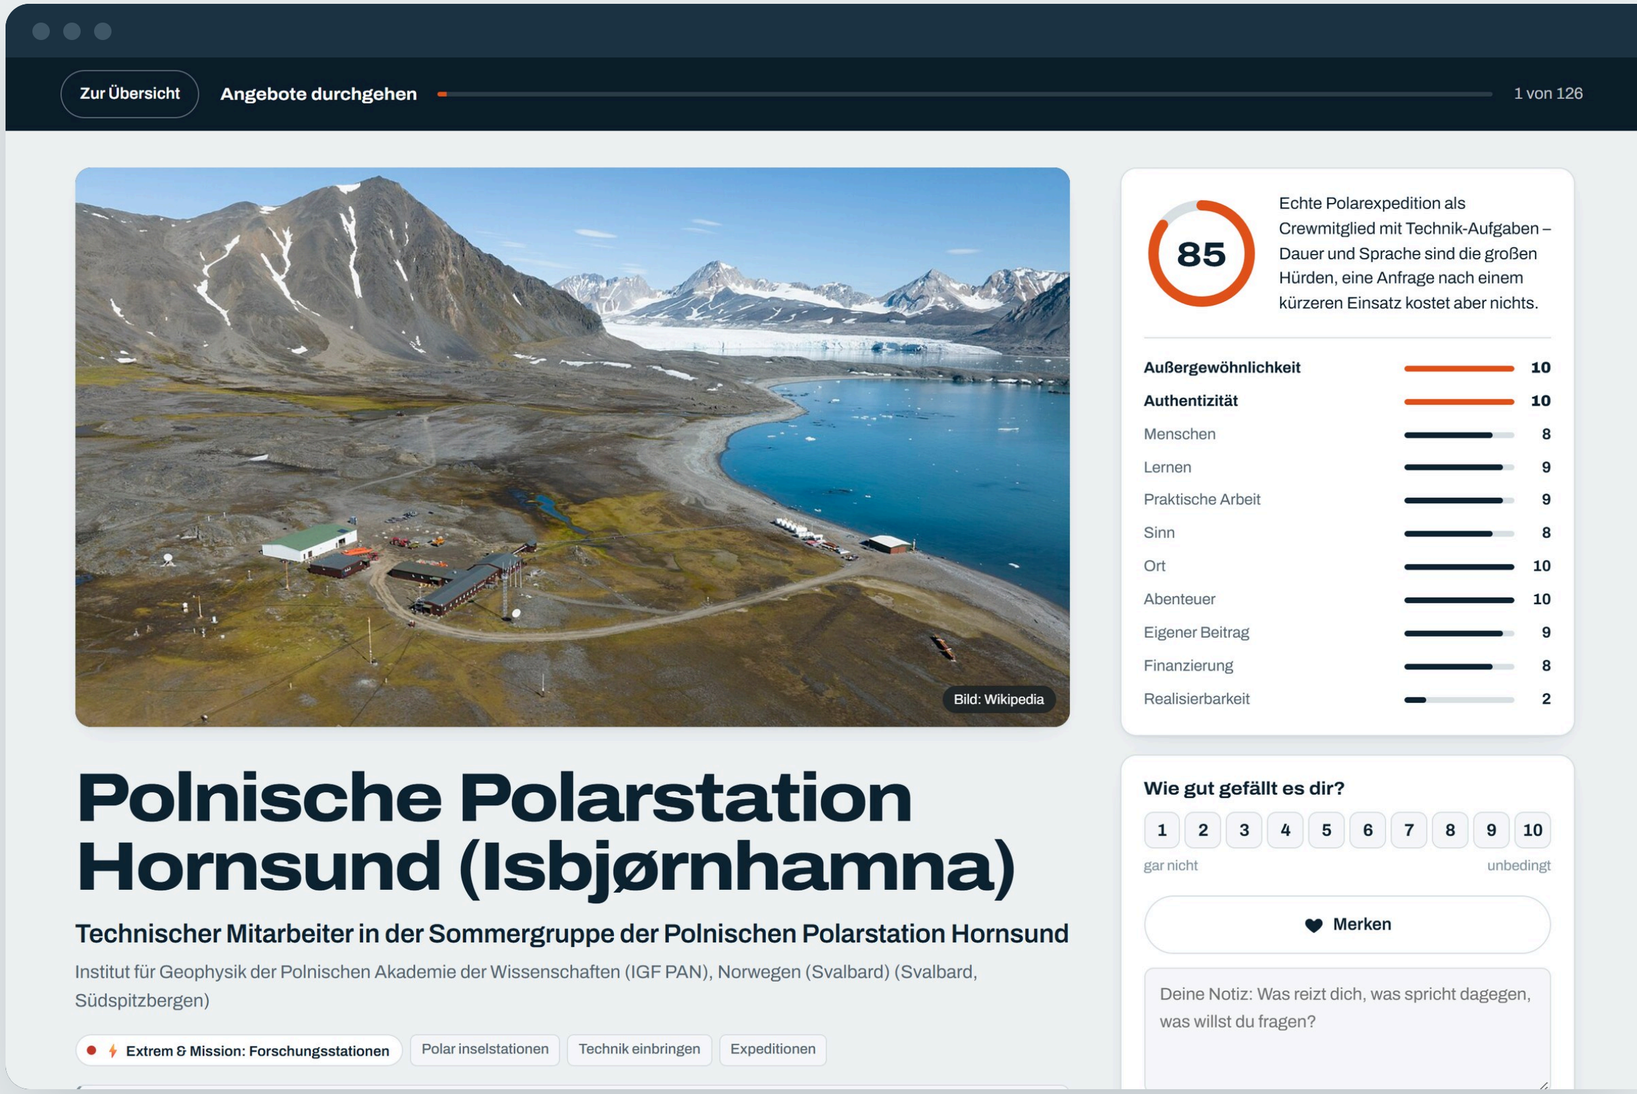

- Filters for pay, accommodation, language and origin
- Unclear costs and fees stand out immediately
- A heart bookmarks an offer for later

Why an offer ranks high

The detail view explains the match in one sentence and shows all eleven criteria individually.

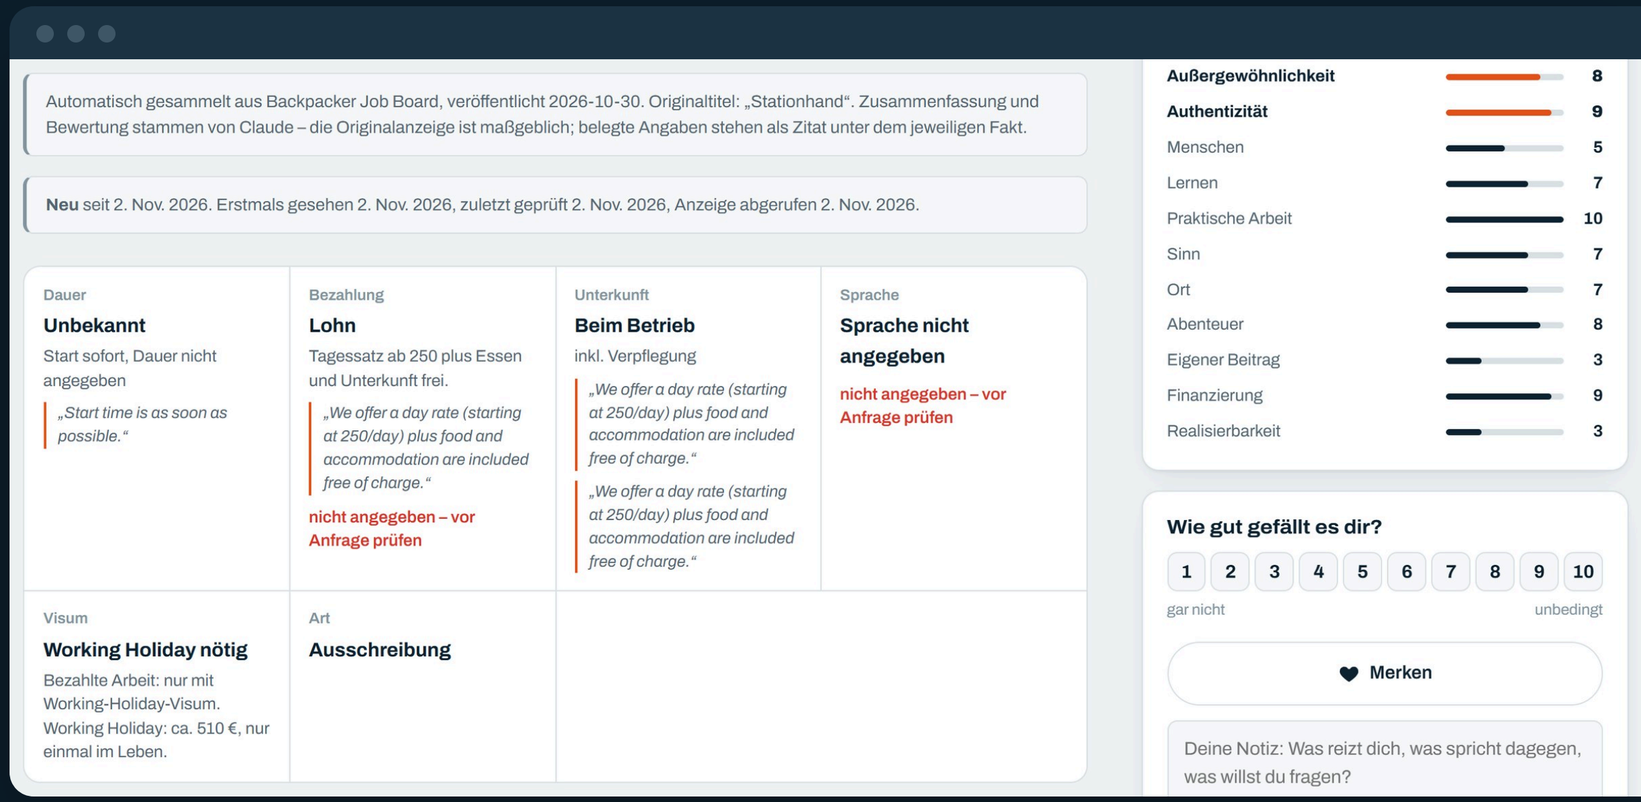

- Extraordinariness and authenticity carry the most weight
- My own rating from 1 to 10, plus notes
- My ratings will later be used to tune the weights

No claim without evidence

Every fact comes with a quote from the original ad. If a detail is missing, it is marked in red.

- The AI must not invent anything: quotes are checked against the ad text
- Visa and cost decisions come from fixed rules, not from the AI
- The original ad always has the final say

Runs by itself every morning

n8n orchestrates, GitHub Actions does the processing, Claude does the assessment. All data lives as JSON in the Git repository.

1

05:00 UTC

Start

n8n triggers the collection run.

n8n

2

from 05:00

Collect and filter

Collectors, state tracking, pre-filter, commit.

GitHub Actions

3

06:00 UTC

AI assessment

Open candidates, one verified quote per fact.

Claude Code Routine

4

afterwards

Prepare

Rules and match scores, matches are calculated.

GitHub Actions

5

afterwards

Notify

New matches and closed bookmarked offers by email.

n8n + Gmail

Watchdog

Checks the status at 09:00 and only reports when something looks off.

Error alerts

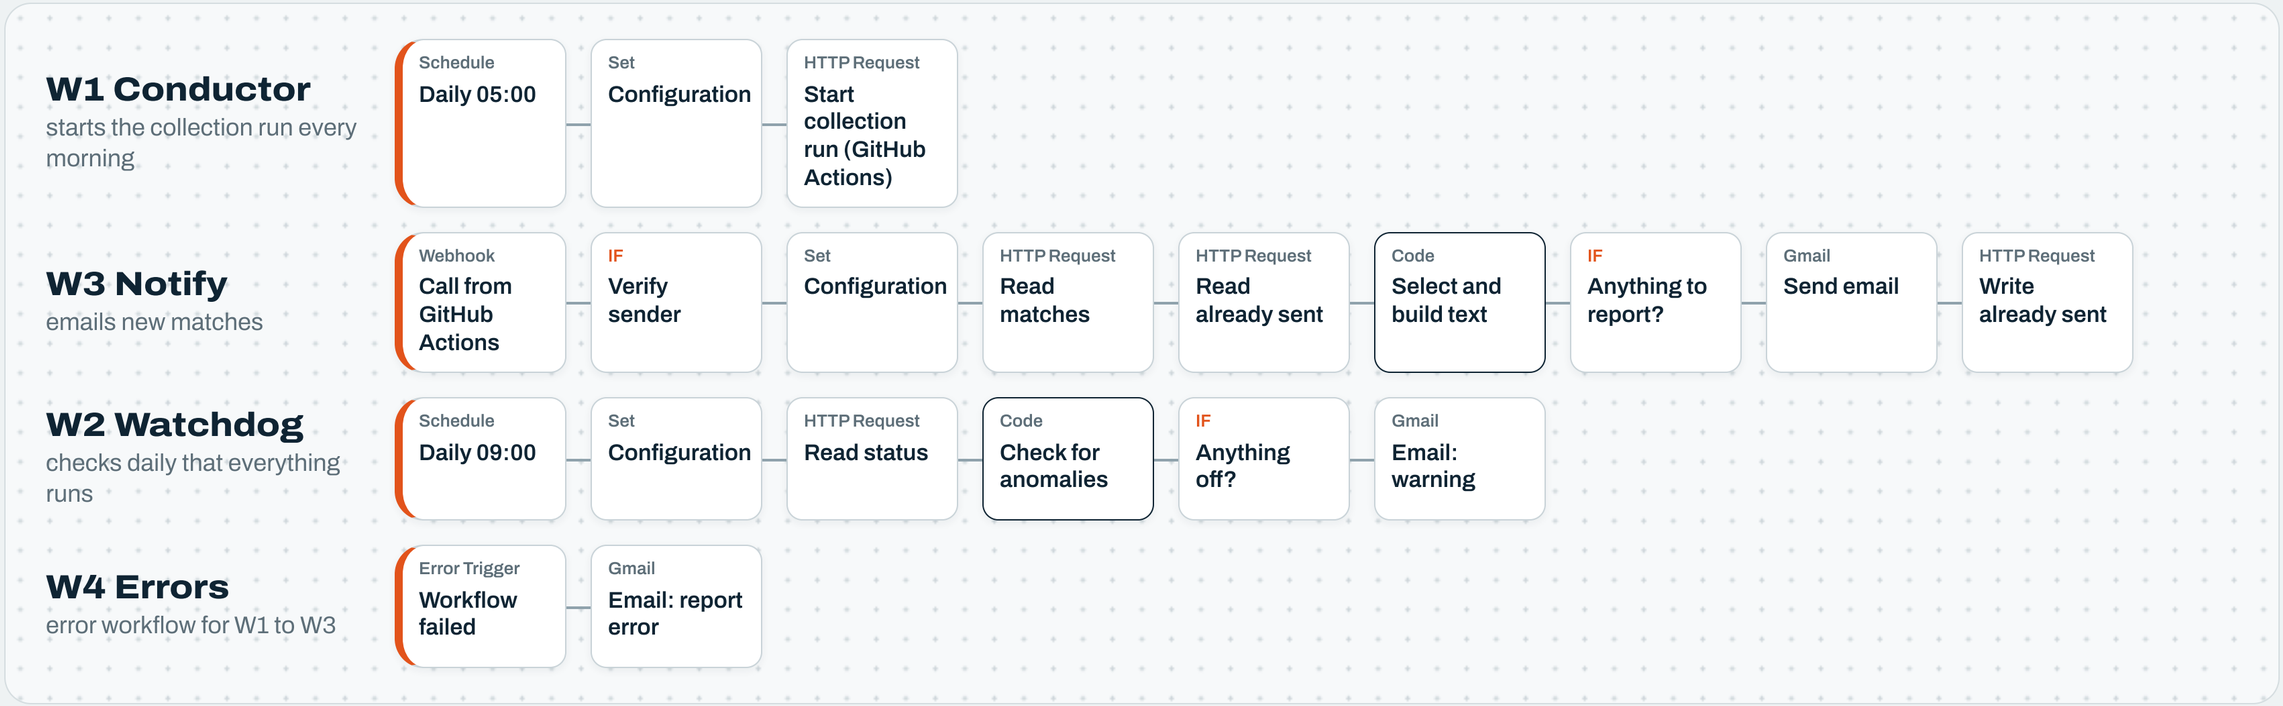

If a workflow fails, an email goes out right away.

Recovery

Collectors are incremental and fault-tolerant, and pick up where the last run stopped.

n8n as the control centre

Four workflows in n8n Cloud handle scheduling, notifications, monitoring and error handling. Processing and assessment stay in GitHub Actions and Claude.

Secured webhook

W3 only accepts calls whose secret matches a SHA-256 hash. n8n only stores the hash.

No duplicate emails

Sent matches are tracked in a JSON file that W3 writes back through the GitHub API.

Speaks up only when needed

Warns if a run is older than 30 hours or a source has delivered nothing for 3 days.

Tested without n8n

The code nodes run in a simulation against real data, including a second run that must stay silent.

As of November 2026

3,129
positions tracked across four sources

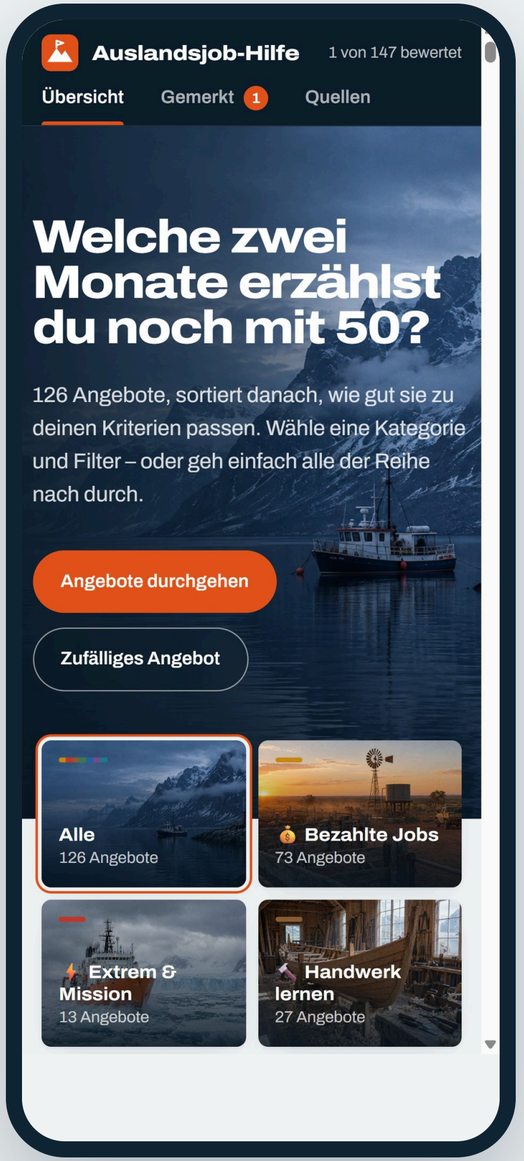

373
candidates after the pre-filter

32
matches reported by email

122
sources researched and assessed

72
offers curated by hand

23
automated tests

How it is built

Python

One collector per source (feed, API, sitemap, HTML), plus a pipeline for state, pre-filter and ranking.

pytest with fixtures from real raw data

Claude Code

A daily routine reads the ads, scores them against the search profile and backs every fact with a quote.

at most 48 assessments per run

n8n

Four workflows: schedule, watchdog, notifications and error alerts.

email via Gmail

GitHub Actions

Collecting and preparing run in the cloud and commit the results to the repository.

runs within the free tier

JSON in Git

No database: state, candidates, matches and ratings are versioned and traceable.

every change is a commit

Web app

A lean Python server and a framework-free front end that works on desktop and mobile.

HTML, CSS, JavaScript
